

Replicating Multi-Account GitHub Push on a New PC

How to set up Git so that `git push origin main` prompts you to choose between two GitHub accounts, matching the current PC's setup.

Why the prompt appears today

The account picker is not a special script or repo setting — it's a built-in feature of **Git Credential Manager (GCM)**, which ships by default with Git for Windows. On the current machine, three things combine to produce it:

- The credential helper is set to `manager` (the Git for Windows default).
- The repository remote uses an **HTTPS** URL (e.g. `https://github.com/<org>/<repo>.git`), not SSH.
- GCM has **two GitHub identities already stored** from previous logins. When it finds more than one cached identity for `github.com`, it shows a picker instead of silently using one.

Confirmed on this machine via `git-credential-manager github list`, which returned two stored accounts. SSH-based remotes bypass GCM entirely and will never trigger this prompt.

Setup steps for the new PC

1 Install / update Git for Windows

Download the latest installer from `git-scm.com`. Git Credential Manager (v2.x) is bundled automatically — no separate install required.

2 Confirm the credential helper is set to `manager`

This is the Git for Windows default, but verify it:

```
git config --system credential.helper
```

If it does not return `manager`, set it explicitly:

```
git config --system credential.helper manager
```

3 Clone / configure the repo with an HTTPS remote

```
git clone https://github.com/<org>/<repo>.git
```

If a repo already exists locally with an SSH remote, switch it to HTTPS:

```
git remote set-url origin https://github.com/<org>/<repo>.git
```

4 Register both GitHub accounts with GCM

GCM only offers a picker once it has more than one cached identity. Add each account explicitly:

```
git-credential-manager github login
```

Run this once and sign in with **account #1** via the browser OAuth prompt. Then run it a second time and sign in with **account #2** (you may need to sign out of the first account in the browser, or use a private/incognito window, so the OAuth screen doesn't auto-select the cached session).

Tip: To verify both accounts registered correctly, run:

```
git-credential-manager github list
```

It should list both usernames, e.g. `manjeshrv592` and `manjesh-simtech`.

5 Push and confirm the picker appears

```
git push origin main
```

Since GCM now sees two stored identities for `github.com`, it will prompt you to choose which account to push as (plus an option to add another account) instead of silently picking one.

Quick reference

Requirement	Command / Check
Git for Windows installed (bundles GCM)	Install from git-scm.com
Credential helper = manager	<code>git config --system credential.helper</code>
Remote uses HTTPS (not SSH)	<code>git remote -v</code>
Two accounts registered in GCM	<code>git-credential-manager github list</code>
